# Yeast 001 — the script, as cut

**13:04 · 118 picks · 23.976p** · rough cut at `build/roughcut/yeast001.roughcut.fcpxml`

This is the read-back of the **assembled cut** — chosen from the word-level transcripts of all fourteen a-cam clips (46 minutes), then punctuated and paragraphed by hand. It is what the video says, in order. Where this page and the audio disagree, the audio wins; the machine read-back of the rendered cut is in `read-back.txt`. Where WhisperX had folded a false start into the word after it, the in-point was re-measured off the audio with `silencedetect` and set exactly — see `make_picks.py`, `exact_start`.

The previous cut (`cuts/intro001/`) was built from the June 9 tapes. **None of that footage is in this cut** — different top, different hair, different framing; it cannot intercut. Everything here is from the June 16 reshoot in `footage/a-cam/`, which was shot against that cut's build sheet and covers all of it except the three pickups listed at the end.

| | |
|---|---|
| **Source** | 46:15 across 14 clips |
| **Cut** | 13:04 (28%) |
| **From MVI_0040** | 5:28 — access and need, budding, chemistry, temperature, sugar |
| **From MVI_0038** | 2:36 — the environment, Pasteur, the one bug, the close |
| **From MVI_0045** | 2:00 — the jars |
| **From MVI_0037** | 1:06 — yeast is old, brewers and bakers |
| **From MVI_0041** | 1:01 — the Pasteur aside |
| **From MVI_0042, 0036, 0043** | 0:50 — sourdough aside, the intro line, the two VO lines |
| **From MVI_0032–0035, 0039, 0044** | nothing — see "What was left out" |
| **Two setups** | **Table** (0036–0039): intro, history, Pasteur, one bug, close. **Kitchen** (0040–0045): the asides, the jars, everything from 7:25 on. |
| **Music** | *Twin Lakes* under the cold open, out by 0:30. *Two Big Reasons* from 12:32, ending on the last frame. Both 16 dB under her, measured 200 Hz–4 kHz. |
| **Framing** | Two static punch-ins (1.08×) hiding jump cuts where both neighbours run ≥ 10 s; four slow pushes (≤ 1.06×) under emphasised lines. All are `adjust-transform` s on the clip, not renders. |
| **Grade** | `assets/luts/yeast001-grade.cube` on every a-cam clip, plus a soft-light lift on her face (preview only). Build sheet §G has the numbers and the Final Cut equivalent. |
| **Pace** | Join pads 80/120 ms; every pause over 0.7 s inside a take trimmed to a 250 ms breath — 49 of them, 48 s. Never below the 120 ms floor [S-002]. |

**The read-back stands at four flags, all accounted for.** Three "repeats" at 0:22, 1:30 and 7:28 are her own parallel phrasing (*we've found it in… we have found it in…*; *if it's a dud batch… if they have a successful batch…*; *why do we have so many names… so many formats*), not two takes. The fourth is the last line ending without a full stop. Eight false starts that earlier read-backs *did* catch are cut out at measured silences; none of them were visible in the transcripts. The pause-tightening pass was diffed word-for-word against the previous read-back: nothing lost but the two paragraphs cut on purpose and one "the, the" stammer.

Timecodes are timeline positions. ⚠ marks a decision or a check needed before lock; each one is in `build-sheet.md` with a fix. **Picture** says what is on screen and what is still wanted there.

---

## Cold open — 0:00

> This is yeast bubbling in action.
>
> And this is me, way too excited about yeast.
>
> You don't actually need sugar to make your yeast grow. You just need time.
>
> Hi, I'm Katie. I'm a food scientist, and this is my deep dive into yeast.

The hook now names a mistake inside six seconds — §9 asked for that and the June 9 cut didn't have it. "You just need time" is the line the whole sugar section at 11:42 pays off.

**Picture.** *Shot 1* is the starter glass from `Best Yeast Broll`, bubbles breaking at the surface. *Shot 2* is Katie dancing, both arms up (`Katie Dancing` @ 0:57) — the clip ends with her walking up to the lens grinning (1:04–1:07), which is the alternate if the dancing reads as too much. *Shot 3* is her in the kitchen, with a slow push to 1.05×. *Shot 4* is the table.

⚠ **The wave.** The first seconds of MVI_0032 are her walking in and sitting down; there is a small hand-to-camera at ~0:08 but it is not a wave. The wave that was under "way too excited" in the June 9 cut is in MVI_0016, which doesn't match this shoot. If you want a wave, the dancing clip at 0:56–1:00 is the nearest thing.

**Graphic.** The title card lands under "my deep dive into yeast" — the first graphic inside 30 s. Rendered as a **placeholder** (flat bone, Kalam): see build sheet §A.

---

## 1. Yeast is old — 0:13

> Yeast is really old. We've had it around for at least a few thousand years. We've found it in archaeological records in Egypt. We have found it in archaeological records in parts of Asia and in Europe.
>
> It's around. It's in our environment. It grows on grapes.
>
> We know that the yeast is in the air around all these ancient people, and so it is just falling into their food — or it's on the grapes that they're smashing up to make wine. It is being pulled in from the environment.

> It's not being inoculated. It's not being pushed into the food by the bakers themselves, until they figure out kind of what's going on: that you need a little bit of something to make something else.
>
> You get the brewers that are taking grapes and grains and turning it into wine and beer and mead. And they're producing these fermenting, bubbly batches of goodness that they like, and they are taking it and they're passing it on to their friends that are making doughs. Those bakers are getting bubbly batches that are making dough that rises, and are different than flat breads, and it's being passed back and forth, back and forth.
>
> With the passing back and forth, you get selective breeding going on. They may not know what they're breeding, but they're being selective about it. If it's a dud batch, they're not passing it on to their friend. If they have a successful batch, they're passing it on to their friend — and the genes of the yeast are being selected for the ones that ferment and make alcohol and raise bread and do lots of things that these ancient people wanted.

This is the version without a date. She recorded "3000 BC, 2000 BC" (MVI_0033) and "about 3,000 years ago" (June 9) and neither is in the cut — "at least a few thousand years" is both true and hers. The timeline card should be as vague as the line under it.

**Cut in the second pass, for pace:** "*The details are a little hazy, because it's hard to extract the DNA and prove that it's yeast with everything else that's mixed into it. That's my understanding. So we just know it's old.*" (MVI_0036 @ 1:02, 13 s) and "*So it's natural that ancient people would have just stumbled upon it*" (MVI_0037 @ 0:55, 6 s). Both charming, both slow, and both sat in the first forty seconds; the second is said again in the next paragraph anyway. If the hazy-DNA line is wanted back, it fits exactly where it was.

**Picture.** Table, one setup, 1:30 unbroken apart from the cuts between takes. It carries four graphics and one piece of b-roll:

- **Timeline card** at 0:18 — Egypt · Asia · Europe as a spread, no dates, torn edge.
- **Wild yeast on grapes** at 0:27 — a macro of the bloom on a dark grape. She names it; it is the one Storyblocks shot worth buying if it can't be shot.
- **The exchange** at 0:52 — the brewer's jar passed to the baker and back. Cardboard, on 2s.
- **Key term** at 1:19 — *Selective breeding*.
- **✗ / ✓** at 1:29 — the dud batch pushed out of frame, the good batch handed on (§6.6).

---

## 2. Louis Pasteur — 1:45

> It wasn't until we meet Louis Pasteur that we have an inkling of what's making one successful batch work, and what's being passed on between these bakers and brewers. He has a gooseneck experiment, and disproves spontaneous generation, and says there are microbes — little bugs that we can't see, all around the world.
>
> If you don't know about the Louis Pasteur experiment: what he does is he takes a glass bulb and stretches out a neck on it, that is open over here, but it has a gooseneck shape. And he heats it up to kill off any bacteria that's on the inside, with some food that he has cooked, that he has put inside of this gooseneck bottle.

> And so if there's any truth to spontaneous generation, the food will just break down. There will be no problem with it doing what food has always done. But if the food breaks down because of germ theory — what he was thinking of is: germs can't get in through the gooseneck bottle. It falls down. It gets stuck in the downspout, right here. So nothing will happen to the food. It won't break down. It won't do anything. And that's what happens.
>
> And so Louis Pasteur proves that there is no spontaneous generation — that there is something in the air: bacteria, yeast, living organisms that are getting into our food and making changes.

⚠ **Meyen is out.** The take that names him — "*After Louis Pasteur, we get to 1838, and Franz Julius Ferdinand Mayen discovers yeast, Saccharomyces cerevisiae specifically*" (MVI_0038 @ 5:51) — is chronologically backwards: the swan-neck work is 1859–61, so 1838 is *before* Pasteur, not after. The spelling is also still "Mayen" (it is Meyen), which was D2 last time. Rather than put a wrong date on a name card, the cut goes from Pasteur's microbes straight to "we meet our *Saccharomyces cerevisiae*", which holds together without him. (The take begins "And so we get Sac— we meet our…"; the in-point is after the stumble.) **One-line pickup** if you want the name back: "*Twenty years before Pasteur's flask, in 1838, Meyen had already given it a name.*" Escalated as D1.

⚠ "because of germ, germ theory" — the stumble is in the cut because the sentence it starts is the one that explains the experiment. If it bothers you, the take at MVI_0041 2:01 has the same sentence without the stumble but trails off afterwards. Two false starts in this chapter are cut at measured silences: "…and that's what happens [and this is why, what, Louis—]" and "[And with the—] And with the discovery" in the next chapter.

**Picture.** The chapter moves from the table to the **kitchen** at 2:07 for the aside ("If you don't know about…") and back to the table at 3:43. That setup change is doing the work of a second camera, and it's motivated: the aside is an aside.

- **Pasteur portrait** at 1:47 — the Nadar photograph (public domain), placed in the left column beside her, never over her face. Rendered and in the timeline.
- **The swan-neck flask** at 2:11 — the Wellcome photograph (CC BY 4.0), same placement, on screen for 10 s while she describes the neck. It has a black background, which §4.1 doesn't allow in a *graphic* — it is here as a reference so the shot can be judged, and the flask should be **drawn or built as a cutout**: it is the single most drawable object in the video.
- **Dust in the bend** at 2:47 — a rust mark settling in the downspout, on the flask drawing, on "it gets stuck in the downspout right here". She points at something off-frame on that line; the graphic is what she's pointing at.

---

## 3. One bug — 3:09

> We meet our *Saccharomyces cerevisiae*. And this is the most common form of yeast that we use today. There are other yeasts that are used in sourdoughs, but for the most part, when you get to industrial bakers, and you get to at-home bakers, and you get to brewers — they're all using the same little bug: *Saccharomyces cerevisiae*.

> *Saccharomyces cerevisiae* is a yeast, which is a member of the fungi family. It's a single-cell organism that lives and thrives and grows in fertile environments.
>
> Now, an aside about sourdough. Sourdough is also using yeast. Most sourdoughs are using *Saccharomyces cerevisiae*, but you'll find in other sourdoughs that there are lots of other different types of yeast involved. It's also using a bacteria that produces lactic acid. And so I'm setting sourdough to the side so we could specifically talk about yeast — but sourdough is using yeast. It is using other forms of yeast that could do the same thing as *Saccharomyces cerevisiae*, but *Saccharomyces cerevisiae* is specifically known for producing repeatable results that do what we want it to do, which is why we use it so much.
>
> And with the discovery of *Saccharomyces cerevisiae*, we move from always needing to have a sourdough-based model — where we have a mother dough, a mother ferment, maintaining our yeast that we pull from to make our doughs — to being able to have on hand just the yeast, and using that, and introducing it into our dough at measured amounts that we want. And our way of baking and our way of brewing changes, because we can be a little bit more intentional with how we are baking and how we are brewing, with being able to measure out the organism that we're introducing into our batches.
>
> *Saccharomyces cerevisiae* is used all over the industries, from alcohol industries to our baking industries — from the big brewers, the big wine makers, the big bakers, to the at-home enthusiasts.

**Picture.** Table → kitchen (the sourdough aside, 3:46–4:28) → table. The 4:28–5:52 stretch is the longest unbroken talking head in the cut and has one graphic in it; it wants the **comparison card** at 4:37 — a mother-ferment jar on the left, a measured packet on the right (§6.6, two items, no more). At 5:52 the insert is the wide of the dry-yeast jars (MVI_0026).

- **Name card** at 3:10 — *Saccharomyces cerevisiae*. This is the recurring card: it comes back identically at 6:49 and is the first word of the close. Set it once.
- **Micrograph** at 3:35 — the SEM of *S. cerevisiae* (CC BY 3.0), left column. Rendered and in the timeline. The fungus line carries a 1.08× punch-in so the cut into it from the long take before doesn't jump.

---

## 4. What's on the shelf — 5:25

> Right here, off camera, I have a couple examples of yeast that you might find when you're out and about looking to buy yeast.
>
> I have some active dry yeast that they actually pre-seeded with sugar. You don't actually need the sugar in there.
>
> I have instant yeast right here. It's a little bit smaller, and so it takes a little bit less for the water to get in and get the yeast going and active and ready to be added into a dough.
>
> I also have a fresh yeast right here. It's ready to go. It's very fragrant. It can just be added straight into a dough. It does have a shorter shelf life. It's more likely to eat through the food source that it has built in with it when it is sold. And so it doesn't last as long on the shelf as, say, the active dry and the instant — which the producers of the active dry and instant have dried it out and made the yeast cells dormant, and less likely to die off.

> I even have this yeast packet right here that is marketed as for mead. And when you look at it, in its ingredients, it is just *Saccharomyces cerevisiae*. All of these things that I just showed you are the same. All of these are the same little bug, the same microbe, the same yeast fungi — they're all *Saccharomyces cerevisiae*.
>
> It's a different way of trying to get it into the hands of those who are looking for it. Because when you're a brewer, you might be looking for brewer's yeast, because you know — that's what I'm doing, that's what I'm looking for. But if you went to the store and bought baking yeast, it would be the same thing. But it might not click that that is what you're looking for.
>
> And so someone with a marketing degree, with a business degree, is saying: hey, let me sell to you. I know what you need. It's this. But it's really all just the same *Saccharomyces cerevisiae*.

⚠ "You don't actually need the sugar in there," ends on a comma — the sentence continues into a triple restart on tape ("but it would just be a… it would just be a…") and is cut before it. Listen to whether the rise at the end reads as a cut. The alternative is to carry on to "…and get started" at MVI_0045 0:57, stumbles and all.

⚠ She says "instant dry yeast" at 0:30 and "instant yeast" again at 0:59 in MVI_0045; the first one is dropped, so the order on screen is active dry → instant → fresh → mead.

**Picture — the insert sequence.** She says "off camera" and means it: the jars are below frame. The b-roll folder has exactly these shots, and they are cut in as split edits:

| TC | Insert | Clip |
|---|---|---|
| 5:32 | jar of dry yeast, close | `MVI_0027` @ 6 s, whole pick |
| 5:39 | shallow jar, fine granules | `MVI_0028` @ 1.5 s, then @ 3.4 s for 5 s after the join |
| 5:51 | fresh yeast cube in the glass | `MVI_0031` @ 1 s, 8 s |
| 6:30 | the mead packet with the jars | `MVI_0029` @ 2 s, 10 s |

Label legibility is the whole point of 6:30 — check the "Mead Yeast" packet reads at 1080p. "It's really all just the same" (7:14) carries a push to 1.06×. The instant-yeast line is two picks (5:39, 5:41): the take has "It's a little bit more… It's a little bit smaller" and the false start is cut out at the measured silence.

---

## 5. Access and need — 7:25

> Why do we have so many different names for it? Why do we have so many different formats for it? The answer is access and need.
>
> You have industrial bakers who don't necessarily want to take the time to reactivate something from being dormant — that want to just use it and move on and get going with their timelines. And you have the at-home baker in the middle of a farm in Kansas that needs something every once in a while, and doesn't want to have to drive two hours back and forth to a grocery store every couple days to get fresh yeast. They need something on hand that they can keep, that won't die off on them as frequently.

> So you have fresh yeast and dry yeast, and you have active dry and instant.
>
> Why doesn't the large baker use the instant yeast? It doesn't need to be reactivated, it doesn't take as long to be reactivated, and it's always on hand. But in the processing of the active dry yeast and the instant yeast, the yeast gets a little damaged, and it can show up in the elasticity of the gluten development. It can shear it a little bit, and it helps dry out the bread a little bit faster — because of this chemical release called glutathione. Glutathione will get into the gluten network and have it break a little bit easier, and it will help the starch release the water a little faster. So you have more of a shorter texture that you might get more of in a sandwich bread, and have it dry out faster.
>
> So having a fresh yeast allows these bakers to have a product that does what they want it to do. It's consistent. It doesn't dry out. And to be honest, an at-home baker might not care. You might not notice. They consume the bread within a couple days, because they're only making one loaf at a time.
>
> So it's about what's available, and what you can use, and what you can find — and what other things are going on in your life, for what matters. Because it might not be worth driving a couple hours to a grocery store to get something to have a bread that's a little bit stretchier that lasts a day longer.

⚠ The glutathione mechanism (E3) and "it might help dry, it helps dry out" at 8:29, which is a self-correction left in because the clean take doesn't exist.

**Picture.** Kitchen from here to the end. Graphics: **key term** *Access and need* at 7:30; the **two bakers** card at 7:43 (a bakery and a farmhouse an hour from a shop, §6.6); **key term** *Glutathione* at 8:38; the **gluten matrix** at 8:43 — long strands, then strands cut short, the clearest before/after in the video. B-roll wanted at 9:00: a cut loaf, stretchy crumb against short crumb.

---

## 6. Budding — 9:30

> If we have so many of the same little *Saccharomyces cerevisiae*, how do we reproduce it? What's going on?
>
> So you have a mother cell that grows, and buds on itself a daughter cell. And when that daughter cell is big and identical to the mother cell, it uses mitosis and splits into two cells.
>
> The yeast will continue to grow and reproduce itself when it's in an environment that has lots of nutrients for it. And those nutrients are sugars and starches. It breaks down starch into sugar.

**Graphic — the budding cycle** at 10:39. Mother, bud, daughter, split. The molecular kit's first real job; the split should land on "splits into two cells", not on a timer. "The yeast will continue" carries a 1.08× punch-in, and starts at a measured silence: the ten seconds before "The yeast will continue" on tape are a stumble ("It grows, does this, this, the…") that WhisperX had folded into a single word.

---

## 7. What it eats — 10:01

> So starch itself will break — flour itself uses an alpha amylase and a beta amylase to break those starches down into sugars that the yeast can digest. The yeast will start digesting sucrose with invertase, and break that down, and use that energy for itself. The yeast will use simple sugars and break it down with the enzyme zymase into $CO_2$ and alcohols.
>
> And the $CO_2$ and the alcohol are the byproducts that we're looking for as humans — either in alcohol production, or in helping our bread rise with the $CO_2$, giving the gas that we will eventually bake off.

⚠ **Chemistry, escalated (E2).** This is better than the June 9 version — amylases now break starch "into sugars", not into sucrose — but the chain as spoken is still *starch → amylases → sugars; sucrose → invertase; simple sugars → zymase → $CO_2$ + alcohol*, and she restarts five times across MVI_0040 6:40–7:33 getting there. She is reading. It cuts together, but **do not build the pathway diagram until she has signed the chain**, because a diagram hardens it.

**Picture.** Pathway graphic at 10:03 and 10:25, blocked on E2. B-roll at 10:37 — dough rising, oven spring — Storyblocks if it can't be shot.

---

## 8. Temperature — 10:43

> Yeast is looking for a right environment for it to thrive and to grow, and that environment has lots of sugars and starches, and is in a temperature between 50 degrees, where it kind of shuts down and goes dormant, and 140 degrees, when it's completely killed off.
>
> There's a nice sweet spot right in the middle — about 93 degrees Fahrenheit, and 100 plus a couple degrees Fahrenheit. And in that sweet temperature spot, it will grow and thrive. And that is the temperature we generally want our bread to be sitting at, to kind of reproduce and proof at the rate that we want it.

⚠ **Numbers, escalated (E1).** 50 °F / 93–102 °F / 140 °F here; the June 9 tape said 54 °F / "just over 100" / 140 °F. Two shoots, two sets of numbers; the gauge can carry only one.

⚠ "between 50 … degrees" — there is a 1.6 s pause after "between" on tape (she loses the thread and picks it up). The take is left whole rather than cut across the pause; the read-back hears "between … 50 degrees" correctly. Worth a listen at 10:53 all the same.

**Graphic — the gauge** at 11:57. One strip: dormant at the bottom, the sweet band, the kill line. Blocked on E1.

---

## 9. Faster and slower — 11:24

> So when we add salt and fat and other spices to our bread doughs, what we're doing is we're putting items in the way of the yeast and its food. And so it's slowing down the process in which the yeast can

> digest the sugars that it wants for growing, and that will then slow our proving time. The availability of sugar will speed up the proofing time.
>
> This is why in active dry yeast they recommend that you add a little bit of sugar, to kind of start the yeast up and going and getting it bubbling. You don't have to actually do that. You can just let it sit a little longer.
>
> Yeast itself just really wants flour and water, and you can do that sometimes by getting a pre-ferment. This is what I have going right here, and it's already starting to bubble up — and it's just flour and water and yeast, and the yeast is in a happy spot.
>
> Adding sugar does speed it up, but then you end up with a sweeter dough. And if that is not the final product that you want, you do not actually need to add sugar to your dough to get the yeast to grow.
>
> The other byproduct of starting with maybe a pre-ferment — a pre-ferment is basically a different version of a sourdough. It lets the yeast get going and multiply, and kind of creates an environment that's easier to add to your dough later. It also, as the yeast breaks down the flour, creates a more complex flavor that might be what you want in your end product.

This is where the hook pays off. "You just need time" at 0:06 → "you don't have to actually do that, you can just let it sit a little longer" at 11:45 → "you do not actually need to add sugar" at 12:17, which carries a push to 1.05×.

**Picture.** Inserts from the b-roll: the tall glass of pre-ferment bubbling at 11:58 (`MVI_0023` @ 14 s, 9 s — she's holding the real jar on that line) and the surface bubbles close at 12:25 (`MVI_0025` @ 20 s, 7 s). Wanted: fat, salt and spice going into a bowl at 11:32; and the **failure-then-fix** shot this whole section is asking for — two doughs, same flour, same clock, one with sugar, one without. Locked-off timelapse. It proves in six seconds what she spends a minute and a half explaining.

---

## 10. The same little bug — 12:48

> *Saccharomyces cerevisiae* is the same little guy that is being used all over the food industry — from the big yeast cakes that you have in the factories, to the little packets that we buy at the store for at-home baking.

Back at the table for the close, with *Two Big Reasons* underneath from 12:32 landing its ending on the last frame, and a slow push to 1.04×. It is the takeaway.

⚠ **The button is missing, and it's the camera's fault.** The take goes on: "*It's the same little bug, Saccharomyces cerevisiae*" — and MVI_0038 stops at 12:07.81, the body's 12-minute clip limit, with "cerevisiae" half said. The read-back hears "it's the same little bug saccharomy—". So the cut ends on "for at-home baking", which is a complete thought, and the last line is a pickup (D1) — the same sentence, said once more, is all it needs. **There is also still no next action** — §9 wants one, under 20 seconds, and nothing on either tape says it.

---

## What was left out, and why

**The Meyen line** (MVI_0038 5:51) — see chapter 2. Wrong date order; pickup offered.

**MVI_0032 (1:10), MVI_0033 (2:07), MVI_0034 (0:41), MVI_0035 (0:42)** — setup, singing "let's talk about yeast", and three earlier passes at "yeast is old" that MVI_0037 does better. 0034/0035 have the "tombs of pharaohs" phrasing if it's wanted; the cut uses "Egypt".

**MVI_0039 (1:50)** — the table version of "why so many names". The cut uses the kitchen version (MVI_0040) because everything after it is kitchen, and a table → kitchen → kitchen → kitchen run is one setup change instead of two.

**MVI_0044 (0:16)** — one false start at the jars.

**The "spontaneous generation was magic" passage** (MVI_0038 2:49–2:47) — four attempts, none complete. The Pasteur aside defines it by showing the experiment instead.

**"And the $CO_2$ and the alcohol … to help our alcohol grow"** (MVI_0040 7:38) — the first of two takes, with the slip. The second is in.

**Every restart.** She restarts a lot — it's normal and it's what the take notes in the FCPXML are for: every join carries a marker saying which take it is and why.

**Stumbles left in.** The read-back hears her restarts inside long takes — "there are other, there are other yeasts"; "they're all using this, they're all using the same little bug"; "you can just add it straight into— it can just be added straight into a dough"; "it's more, it's more likely"; "on them— on the shelf"; "which had — which the producers"; "because of germ, germ theory"; "in the, in the downspout". Each is a few hundred milliseconds inside a take that is otherwise the best one. Cutting them out means a jump cut mid-sentence; they are left for you to decide on in the timeline, where each one is a marker away.

**Three pickups, not recorded on either shoot:** the close's last line and a next action (D1); the Meyen sentence in the right order (D2); and an outro ask of any kind. Everything else on the June 9 build sheet is covered.
